

maXbox starter 86

Python for Delphi (P4D) is a set of free components that wrap up the Python DLL into Delphi and Lazarus (FPC). A DLL could be for example the 'python37.dll'. They let you almost easily execute Python scripts, create new Python modules and new Python types. You can create Python extensions as DLLs and much more like scripting or automating your console. P4D provides different levels of functionality:

- Low-level access to the Python API
- High-level bi-directional interaction with Python
- Access to Python objects using Delphi custom variants (VarPyth.pas)
- Wrapping of Delphi objects for use in Python scripts using RTTI (WrapDelphi.pas)
- Creating Python extension modules with Delphi classes, records and functions
- Generate Scripts in maXbox from a Python engine.

P4D makes it, after some (tough) studies, very easy to use Python as a scripting language for Delphi applications. It also comes with an extensive range of demos and useful (video) tutorials. So a very first simple approach is to call the Python dll without a wrapper or mapper e.g. call the copyright function:

```
// if fileExistst(PYDLLPATH+ 'python37.dll';
function getCopyright: Pchar;
external 'Py_GetCopyright@C:\maXbox\EKON25\python37.dll stdcall';
```

Then we call the function with a pre-test:

```
function IsDLLOnSystem(DLLName:string): Boolean;
var ret: integer; good: boolean;
begin
  ret:= LoadLibrary(pchar(DLLNAME));
  Good:= ret>0;
  if good then FreeLibrary(ret);
  result:= Good;
end;
if isDLLOnSystem(PYDLLPATH+PYDLLNAME) then begin
  showmessage('py dll available');
  writeln(getCopyright)
end;
```

We also use to invoke a Python script as an embedding const and use the dll functionality of `Import('PyRun_SimpleString');`

```
procedure InitSysPath;
var _path: PPyObject;
    const Script =
        'import sys' + sLineBreak+
        'sys.executable = r"%s"' + sLineBreak+
        'path = sys.path' + sLineBreak+
        'for i in range(len(path)-1, -1, -1):' + sLineBreak+
        '    if path[i].find("site-packages") > 0:' + sLineBreak+
        '        path.pop(i)' + sLineBreak +
        'import site' + sLineBreak+
        'site.main()' + sLineBreak+
        'del sys, path, i, site';
begin
    if VenvPythonExe <> '' then
        ExecString(AnsiString(Format(Script, [VenvPythonExe])));
    _path := PySys_GetObject('path');
    if Assigned(FOnSysPathInit) then
        FOnSysPathInit(Self, _path);
end;
```

HOW TO USE PYTHON4DELPHI

The best way to learn about how to use P4D is to try the extensive range of demos available. Also studying the unit tests for VarPyth and WrapDelphi can help understand what is possible with these two units and the main PythonEngine.pas.

Lets start with the VarPyth.pas unit.

This allows you to use Python objects like COM automation objects, inside your Delphi source code. This is a replacement, bugfixed of the former PythonAtom.pas that uses the new custom variant types introduced since Delphi6.

You may use these Python Variants in expressions just as you would any other Variants or automation e.g.:

```
var
    a: Integer; v: Variant;
begin
    v:= VarPythonEval('2 ** 3');
    a:= v;
```

The functions provided by this unit `VarPyth.pas` are largely selfexplanatory.

WHAT ABOUT THE `WrapDelphi.pas` UNIT?

You can use P4D to create Python extension modules too that expose your own classes and functions to the Python interpreter. You may package your extension with `setuptools` and distribute it through `PyPi`.

So if you have an existing object or unit in Delphi that you'd like to use in Python but you don't want to modify that object to make it Python-aware, then you can wrap that object just for the purposes of supplying it to Python with a package. Using `TPyDelphiObject` you can wrap any Delphi object exposing published properties and methods.

Note that the conditional defines `TYPEINFO` and `METHODINFO` need to be on. As an example, if you have an existing Delphi class simply called `TRGBColor`:

```
TRGBColor = class
  private
    fRed, fGreen, fBlue: Integer;
  public
    property Red: read fRed write fRed;
    property Green: read fGreen write fGreen;
    property Blue: read fBlue write fBlue;
end;
```

You want to use `Color` within some Python code but you don't want to change anything about the class. So you make a wrapper inherited from `TPyObject` that provides some very basic services, such as getting and setting attributes of a `Color`, and getting a string representation:

```
TPyColor = class(TPyObject)
  private
    fColor: TRGBColor;
  public
    constructor Create( APythonType: TPythonType ); override;
    // Py Basic services
    function GetAttr(key: PChar): PPyObject; override;
    function SetAttr(key: PChar; value: PPyObject): Integer; override;
    function Repr: PPyObject; override;
end;
```

The project in the subdirectory Delphi generates a Python extension module (a DLL with extension “pyd” in Windows) that allows you to create user interfaces using Delphi from within Python. The whole VCL (almost and maybe) is wrapped with a few lines of code! The small demo TestApp.py gives you a flavour of what is possible. The machinery by which this is achieved is the WrapDelphi unit.

The subdirectory DemoModule demonstrates how to create Python extension modules using Delphi, that allow you to use in Python, functions defined in Delphi. Compile the project and run test.py from the command prompt (e.g. py test.py). The generated pyd file should be in the same directory as the Python file. This project should be easily adapted to use with Lazarus and FPC.

The subdirectory RttiModule contains a project that does the same as the DemoModule, but using extended RTTI to export Delphi functions. This currently is not supported by FPC. The unit PythonEngine.pas is the main core-unit of the framework. You are responsible for creating one and only one TPythonEngine. Usually you just drop it on your main form. Most of the Python/C API is presented as member functions of the engine.

```
type
  TPythonVersionProp = record
    DllName : string;
    RegVersion : string;
    APIVersion : Integer;
  end;
...
Py_BuildValue := Import('Py_BuildValue');
Py_Initialize := Import('Py_Initialize');
PyModule_GetDict := Import('PyModule_GetDict');
PyObject_Str := Import('PyObject_Str');
PyRun_String := Import('PyRun_String');
PyRun_SimpleString := Import('PyRun_SimpleString');
PyDict_GetItemString := Import('PyDict_GetItemString');
PySys_SetArgv := Import('PySys_SetArgv');
Py_Exit := Import('Py_Exit');
...
```

Let's take a last look at the functionality of PyRun_SimpleString mentioned first within the const script.
http://www.softwareschule.ch/examples/1016_newsfeed_sentiment_integrate2.txt

```
PyRun_SimpleString: function(str: PAnsiChar): Integer; cdecl;
```

We see that we have to pass a PAnsiChar in cdecl convention and map to ExecString (PyRun_String):

```
procedure TPythonEngine.ExecString(const command: AnsiString);
begin
  Py_XDecRef( Run_CommandAsObject( command, file_input ));
end;
```

CONCLUSION

The P4D library provides a bidirectional bridge between Delphi and Python.

It allows Delphi applications to access Python modules and run Python scripts.

On the other side it makes Delphi/Lazarus objects, records, interfaces, and classes accessible to Python, giving Python the ability to use this methods.

Before you try the demos please see the Wiki topic "How Python for Delphi finds your Python distribution" at <https://github.com/pyscripter/python4delphi/wiki/FindingPython>

You will need to adjust the demos accordingly, to successfully load the Python distribution that you have installed in your PC, e.g. C:\Users\max\AppData\Local\Programs\Python\Python36\.

PYTHONENGINE:

The core of Python for Delphi. Provides the Python API with dll mapper and runtime configuration.

VarPyth: VarPyth wraps Python types as Delphi custom variants.

WrapDelphi: Uses RTTI (in a DLL) so you can use Delphi objects from Python without writing individual wrapper classes or methods.

TPythonGUIInputOutput: Provides a Python console you can drop on a form and execute a Python script from a memo. The TPythonEngine class is the single global engine block shared by all Python code.

VarPyth wraps Python types as Delphi custom variants.

VarPyth requires at least Delphi v6.

This Tutorials folder contains text and video, webinar tutorials accompanied with slides and demo source code. Next time I'll show a few bidirectional demos with implementation details.

Dealing with internals of Python means also you get the original stack-trace errors back like

```
(TPythonEngine.RaiseError;): File
C:\Users\max\AppData\Local\Programs\Python\
Python36\lib\sitepackages\pandas\core\indexing.py,
line 1304, in
_validate_read_indexer raise KeyError(f"{not_found} not in index")
KeyError: "['id', 'links', 'published_parsed', 'published',
'title_detail', 'guidislink', 'link', 'summary_detail'] not in index"
```

Python distribution that you have installed on your computer. Doc: <https://maxbox4.wordpress.com>

APPENDIX: CATALOG OF THE DEMOS:

Demo01 A simple Python evaluator
 Demo02 Evaluate a Python expression
 Demo03 Defining Python/Delphi vars
 Demo04 Defining Python/Delphi vars (advanced case)
 Demo05 Defining a new Module
 Demo06 Defining a new Type
 Demo07 Using Delphi methods as Python functions
 Demo08 Using Delphi classes for new Python types
 Demo09 Making a Python module as a Dll
 Demo10 FireDAC Database demo using FireDAC
 Demo11 Using Threads inside Python
 Demo16 Using a TDelphiVar or Module methods
 Demo17 Using variant arrays of 2 dimensions
 Demo19 C++ Builder: this is a replicate of the Delphi Demo05
 Demo20 C++ Builder: this is a replicate of the Delphi Demo08
 Demo21 Using Events in TPythonModule or TPythonType
 Demo22 Using Threading, Windows Console and Command line arguments
 Demo23 Using Threading and Delphi log window
 Demo25 Using VarPyth.pas
 Demo26 Demo08 revisited to allow the new Python type to be subclassed
 Demo27 Container indexing
 Demo28 Iterator
 Demo29 Using Python Imaging Library (PIL)
 Demo30 Using Named Parameters
 Demo31 Using WrapDelphi to access Delphi Form attributes
 Demo32 Demo08 revisited using WrapDelphi
 Demo33 Using Threads inside Python
 Demo34 Dynamically creating, destroying and recreating PythonEngine.
